- 1. Consider an asset which follows a geometric Brownian motion (GBM) with drift  $\mu=10\%$  and volatility  $\sigma=20\%$ . Assume that the risk free rate is r=5%. The initial asset price at time t=0 is S(0)=100.
  - Simulate 10 different paths of the asset price making use of the GBM, in both the real and the risk-neutral worlds.
  - Now compute the price of a six month fixed-strike Asian option with a strike price of 105 (using arithmetic average). Do the pricing for both call and put options, using Monte Carlo simulation.
  - Repeat the above exercise with strike price K=110 and K=90. How do your results compare ?
  - Now do a sensitivity analysis of the option prices.
- 2. Compute the prices of the Asian options given above by employing variance reduction techniques also and compare your results.
